

Dear Akkio team,

Your description of agentic coding as "Tuesday" is why I'm applying. I've spent the last year rebuilding my own workflow around agents and clearing them for production use inside insurance (maybe the most risk-averse industry there is), so the standard for quality/testing/reliability is one I already maintain.

At Pharmacists Mutual I led agentic coding adoptions for the data and software engineering teams: running the evaluation, writing the security framework, shipping agent-assisted work into production. I built a custom SQL Server MCP so that our data team could use Claude Code to (safely) query DEV, UAT, and PRD. The result was roughly 60% faster story delivery. That combination of aggressive AI adoption and hard security controls maps directly to the on-premises, agency cloud, inherited permissions work you described in your job post.

On the personal side: my portfolio spans FastAPI and Node/Express services with hand-rolled auth/session/rate-limiting, React front ends with custom Canvas renderers, Postgres/Mongo/DuckDB schemas, OpenTofu, containers, GitHub Actions, several OVHCloud VPS servers to run it all (they're under \$10/month, and more than enough for the workloads), and the final hosting on Cloudflare. I built every single one as an "agent-first" workflow, with maintained context files and agent co-authored commits - I can speak concretely about where agents fail and how I verify their output. I'd fit full stack best, with data as a second specialty.

I'm interested especially in your description of ownership. I've been owning data and software systems for the last 9 years, most recently as sole technical decision-maker on data, reporting to our leadership team. I'd bring that same skillset to the systems behind your agents. I'd love the chance to chat.

All the best,
Sander VanWilligen
